WARNING TO THE READER

This technical note was written by a "non_biochemist" who misuses the registered term "total biomass".

In the present note, when it appears in the figures, the term "total biomass" means, exceptionally, the biomass produced by the equations of biosynthesis of biomass of TN 27.1 and recalled hereafter, for Nitrosomonas and Nitrobacter, respectively :

In the text, the biomass produced by these reactions is called "global biomass" or "X_G".

In the same way, the term "visible biomass" or "X_v" in the figures means "the biomass fixed on the beads". In the text, it is called "active biomass".

SIMPLIFICATION OF THE DYNAMIC MODEL OF THE NITRIFYING COMPARTMENT

1. INTRODUCTION

The dynamic model built by the University of Clermont Ferrand (TN 27.1 and 27.2) is a "first principles" model based on biology, chemistry and physics. It takes into account a lot of compounds to describe the complexity of the phenomena. The author of this model, L. Poughon, noticed that the computation time was huge when the gas NH_3 is involved in the description of the reactions.

As this paper will show it, this huge computation time is due to very short time constants, particularly for NH_3

The first step of this study is to replace the non linear rigorous law of the gas-liquid equilibrium by an approximate linear one. Then, the system of equations can be solved explicitly and the short time constants removed.

In order to reach this aim, the substrates of the problem are divided into 2 parts :

- ◆ those which are present in two phases : O_2 , CO_2 and NH_3
- ◆ those which are present only in liquid phase : NO_2^- , NO_3^- , HPO_4^{2-} and SO_4^{2-}

N.B. : This work is limited to TN 27.1 and TN 27.2 of LGCB and does not take into account :

- ◆ the inhibitory effect of NO_2^- and NO_3^- on the Nitrobacter growth (introduced in TN 27.3)
- ◆ a biofilm diffusion model (introduced in TN 27.3)
- ◆ metabolism and growth of Nitrosomonas and Nitrobacter in presence of organic matter (introduced in TN 32.1)

2. NOTATION

For each substrate of the problem

- a : molar concentration in the gas phase
- b : molar concentration in the liquid phase
- c : molar concentration at the thermodynamical equilibrium
- d_G : molar concentration in the incoming gas flow
- d_L : molar concentration in the incoming liquid flow
- q_G : gas flow rate (1/h)
- q_L : liquid flow rate (1/h)
- r : production or consumption rate (mol/1/h)
- K : volumetric transfer coefficient in liquid phase (notation KLa in TN 27.1)
- k : partition coefficient of gas-liquid equilibrium

With this notation, each variable is considered as a vector whose components are the corresponding values of the substrates. For example, a is the vector of the molar concentrations of the substrates (O_2 , CO_2 and NH_3) in the gas phase. The product of 2 vectors is a term by term product (and not a vectorial product). All these concentrations are in mol/1.

For each part of the column (A or tank n of B or C) the volumes are :

- V_G : volume of gas (beads not included, for part B)
- V_L : volume of liquid (beads not included, for part B)

3. SIMPLIFIED SYSTEM OF EQUATIONS OF THE BI-PHASES SUBSTRATES

Considering any part of the column (part A or C or any tank of B) :

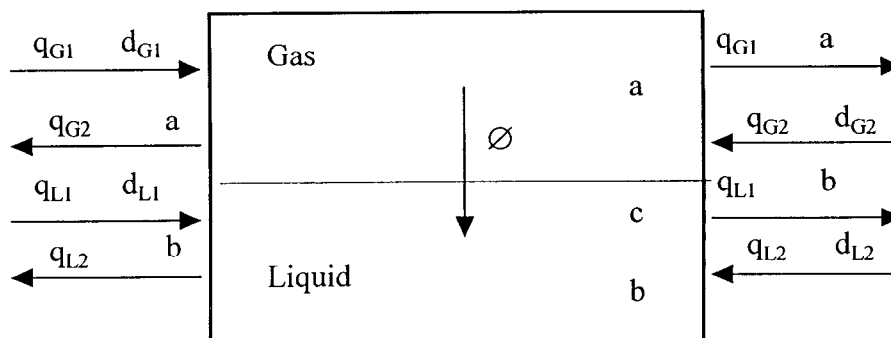

Figure 1 : Concentrations and mass fluxes of any part of the column

ESA - ESTEC	MELISSA - Technical note 35.2		April 1998
	"Simplification of the dynamic model of the nitrifying compartment"		N° réf : 2034

			Disquette PC n°51
			Page 4

The indices 1 and 2 are :

- 1 : for flow from left to right hand side ;
- 2 : for flow from right to left hand side.

The process is described by the 4 following equations.

With the assumptions of perfect gases, the gas-liquid equilibrium is written (justification in Annex 1) :

$$a = \alpha \cdot c \quad \text{with : } \alpha = \frac{k}{n_o \cdot V_M} \quad (1)$$

$$n_o = 55.56 \quad (\text{number of mols in a liter of water})$$

$$V_M = 24.86 \quad (\text{molar volume under 1 atmosphere and 303 K})$$

The mass flux, \emptyset , from gas to liquid is :

$$\emptyset = K(c-b) \quad (2)$$

The mass conservation in the gas is :

$$V_G \cdot \frac{da}{dt} = -\emptyset \cdot V_L + q_{G1}(d_{G1} - a) + q_{G2}(d_{G2} - a) \quad (3)$$

The mass conservation in the liquid is :

$$V_L \cdot \frac{db}{dt} = (r + \emptyset) \cdot V_L + q_{L1}(d_{L1} - b) + q_{L2}(d_{L2} - b) \quad (4)$$

So, given the following new input variables q_G , q_L , d_G and d_L :

$$q_G = q_{G1} + q_{G2}$$

$$q_L = q_{L1} + q_{L2}$$

$$q_G \cdot d_G = q_{G1} \cdot d_{G1} + q_{G2} \cdot d_{G2}$$

$$q_L \cdot d_L = q_{L1} \cdot d_{L1} + q_{L2} \cdot d_{L2}$$

the previous system of equations becomes a system of 4 equations with 4 unknowns (a, b, c and \emptyset) :

ESA -ESTEC	MELISSA - Technical note 35.2		April 1998
	"Simplification of the dynamic model of the nitrifying compartment"		N° réf : 2034
ADERSA	10, rue de la Croix Martre	Tel : (33) 01 60 13 53 53	Disquette PC n°51
	91873 PALAISEAU Cedex	E-Mail : adersa@adersa.asso.fr	Page 5

$$a = \alpha \cdot c \quad (5)$$

$$\emptyset = K(c-b) \quad (6)$$

$$V_G \cdot \frac{da}{dt} = -\emptyset \cdot V_L + q_G (d_G - a) \quad (7)$$

$$V_L \cdot \frac{db}{dt} = (r + \emptyset) V_L + q_L (d_L - b) \quad (8)$$

Using Laplace transforms and cancelling a, c and Φ lead to a relation between the inputs of the problem r, d_G , d_L and the output b (full details in Annexe 2) :

$$(1 - \alpha_1 \alpha_4) (1 + \tau_1 p) (1 + \tau_2 p) \cdot b = \alpha_2 (1 + \theta_2 p) \cdot r + \alpha_1 \alpha_5 \cdot d_G + \alpha_3 (1 + \theta_2 p) \cdot d_L \quad (9)$$

where the time constants τ_1 , τ_2 and θ_2 and the scalars α_1 , α_2 , α_3 , α_4 and α_5 are functions of the parameters α , K, V_L , V_G , q_L and q_G .

Two simplifications may be done.

First simplification : as figure 2 shows it, $\frac{\theta_2}{\tau_2} \simeq 1$. So $1 + \tau_2 \cdot p \simeq 1 + \theta_2 \cdot p$.

Second simplification : as figure 3 shows it, the ratio $\frac{\tau_2}{\tau_1}$ is small (the biggest value of this ratio is 0.07). So the second order transfer is nearly equal to a first order transfer :

$$(1 + \tau_1 p) (1 + \tau_2 p) \simeq 1 + \tau_1 \cdot p$$

So the relation (9) becomes :

$$(1 - \alpha_1 \alpha_4) (1 + \tau_1 p) \cdot b = \alpha_2 \cdot r + \alpha_1 \cdot \alpha_5 \cdot d_G + \alpha_3 \cdot d_L \quad (10)$$

A similar expression is obtained for the concentration in the gas phase, a.

Using the inverse Laplace transforms, the derivatives of a or b are :

$$\frac{db}{dt} = \frac{1}{\tau_1} (-b + G_1 \cdot d_L + G_2 \cdot d_G + G_3 \cdot r) \quad (11)$$

		Fax : (33) 01 69 20 05 63	

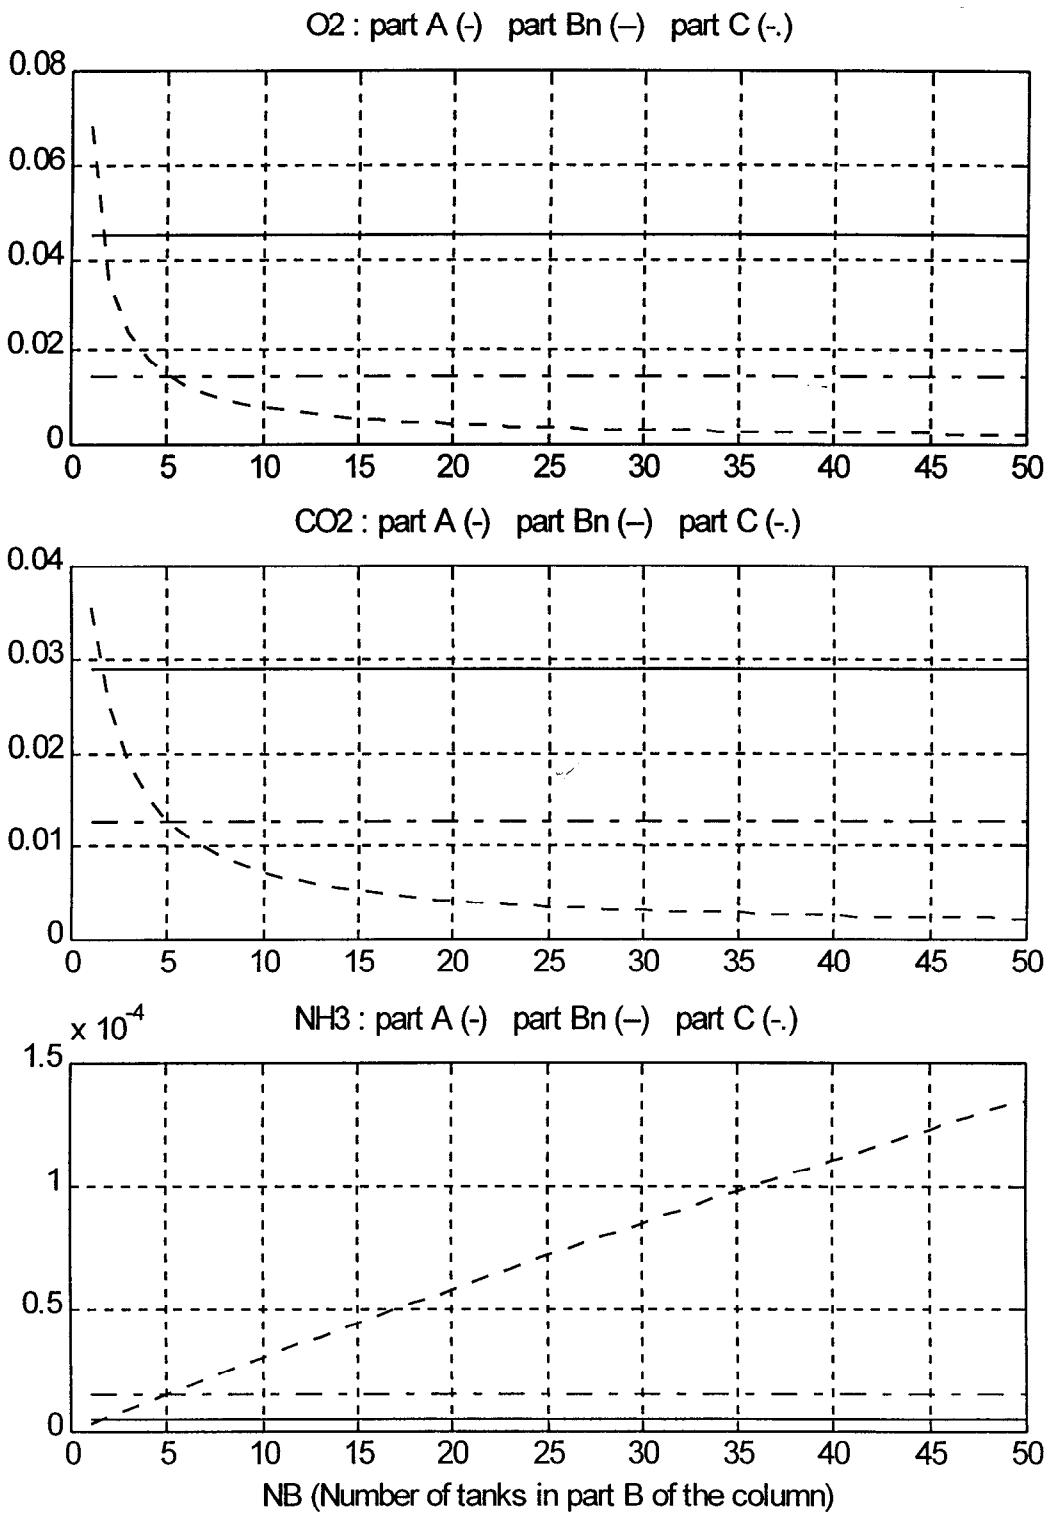

Figure 3 : Time constants ratio $\frac{\tau_2}{\tau_1}$

Computation time and memory allocation

The computation time and memory allocation have been compared for a first order and a second order transfer for the part B of the column with $N_B = 1$.

With this configuration, the ratio $\frac{\tau_2}{\tau_1}$ is maximum for O₂ and CO₂ and minimum for NH₃ (values given in table 1).

Bi-phases compound	τ_1 (h)	τ_2 (h)	$\frac{\tau_2}{\tau_1}$
O ₂	$1.97 \cdot 10^{-2}$	$1.35 \cdot 10^{-3}$	$6.85 \cdot 10^{-2}$
CO ₂	$2.80 \cdot 10^{-2}$	$9.44 \cdot 10^{-4}$	$3.37 \cdot 10^{-2}$
NH ₃	$7.48 \cdot 10^{-1}$	$1.99 \cdot 10^{-6}$	$2.65 \cdot 10^{-6}$

Table 1 : Time constants of part B with $N_B = 1$

Figure 4 shows the step responses of these 2 transfers. There is a slight difference for O₂ and CO₂ during the transient behaviour, but no difference at all for NH₃. Moreover, for this last compound, the second order transfer needs more than 10 000 times the computation time and the memory allocation of the first order one (table 2).

Bi-phases Compound	First order		Second order		ratio second order versus first one	
	CT1 (s)	MA1	CT2 (s)	MA2	$\frac{CT2}{CT1}$	$\frac{MA2}{MA1}$
O ₂	$5 \cdot 10^{-2}$	66	$6 \cdot 10^{-2}$	81	1.2	1.23
CO ₂	$5 \cdot 10^{-2}$	60	$6 \cdot 10^{-2}$	75	1.2	1.25
NH ₃	$5 \cdot 10^{-2}$	64	514	684034	10^4	$1.07 \cdot 10^4$

Table 2 : Computation time (CT) and memory allocation (MA) of figure 4.

N.B : The memory allocation is the number of points of the simulation horizon of figure 4 : 0.15 hour for O₂ and CO₂, 5 hours for NH₃.

From this example that covers all the variation range of the ratio τ_2/τ_1 , it is clear that the first order transfer is quite equivalent to the second one, for all the bi-phases compounds and for $1 \leq N_B \leq 50$.

4. EQUATIONS OF THE MONO-PHASE SUBSTRATES

For the substrates only present in liquid phase (NO_2^- , NO_3^- , HPO_4^{2-} and SO_4^{2-}), the derivative of the concentration is :

$$\frac{db}{dt} = \frac{1}{\tau_L} (-b + \tau_L \cdot r + d_L) \quad (13)$$

with $\tau_L = \frac{V_L}{q_L}$

Figure 5 shows that, for O_2 and CO_2 , and for N_B between 1 and 5, the time constant τ_1 can be neglected versus τ_L . But, in a general way, τ_1 cannot be neglected versus τ_L .

5. SIMULATION

5.1. Configuration of the simulation

The configuration of the simulation are those of TN27.2 (L. Poughon, Laboratoire de Génie Chimique Biologique) :

- standard configuration described p.12 and 13 ;
- number of equivalent tanks in the fixed bed : 5
- stoichiometries p.3 ;
- dissociation constant of $\text{CO}_2/\text{HCO}_3^-$ p.2 ;
- limiting substrates defined p.4 ;
- no inhibitory substrate ;
- no limitation due to liquid/biofilm transfer
- transfer coefficient $K_{\text{L}}a = [51 \quad 51 \quad 500] \text{ h}^{-1}$
for $\text{O}_2 \quad \text{CO}_2 \quad \text{NH}_3$
- partition coefficient $k = [45990 \quad 1853.1 \quad 11.349]$
for $\text{O}_2 \quad \text{CO}_2 \quad \text{NH}_3$ (non ionic form)

The compounds involved in the simulation are :

- O_2 G(Gas phase) and L(Liquid phase)
- CO_2 G and L
- NH_3 G and L
- HCO_3^-
- NO_2^-
- NO_3^-
- HPO_4^-
- SO_4^-
- X_{N_s} (biomass Nitrosomonas, active and global (active + decay))
- X_{N_b} (biomass Nitrobacter, active and global (active + decay))

5.2. Results

Figure 6 to 9 are composed of 8 graphs whose the last one (below right hand side) is common to all the figures and shows the average active biomass concentration in the fixed bed. The 7 other graphs are connected to tank 1 (of the fixed bed) in the figures 6 and 8, and to tank 5 (the last one of the fixed bed) in the figures 7 and 9.

The figures 8 and 9 are abscissa zooms of figures 6 and 7, respectively.

			Disquette PC n°51 Page 14

The composition of the gaz phase (G notation) is given in molar fraction (mf), the composition of the liquid phase (L notation) is given in mol/l or g/l (for biomass).

■ **Tank 1 of fixed bed :**

During the 29 first hours, no substrate is limiting for biomass N_s and the growth of this biomass is exponential while the concentrations of substrates HCO_3^- , O_2 and NH_3 are decreasing exponentially. At the beginning, NO_2^- is limiting for N_b and this biomass is slightly decreasing. After several hours its growth is exponential.

At time $t = 29h$, the NH_3 concentration (0.4 mmol/l) becomes limiting : the growth of biomass bends, so that the consumption of HCO_3^- is decreasing (CO_2 concentration reaches a minimum). On the contrary, NO_2^- concentration is maximum (2 mmol/l) : the consumption of NO_2^- by N_b becomes greater than its production by N_s .

The O_2 concentration goes on decreasing slowly (until 0.125 mmol/l at the end of the simulation) as the active biomass N_s and N_b is nearly becoming stabilized. The NH_3 -L and NO_2^- concentrations are nearly stabilized at 0.02 and 0.15 mmol/l. During the last 150 h, NH_3 -G is decreasing slowly from $5 \cdot 10^{-5}$ to $2 \cdot 10^{-5}$ molar fraction.

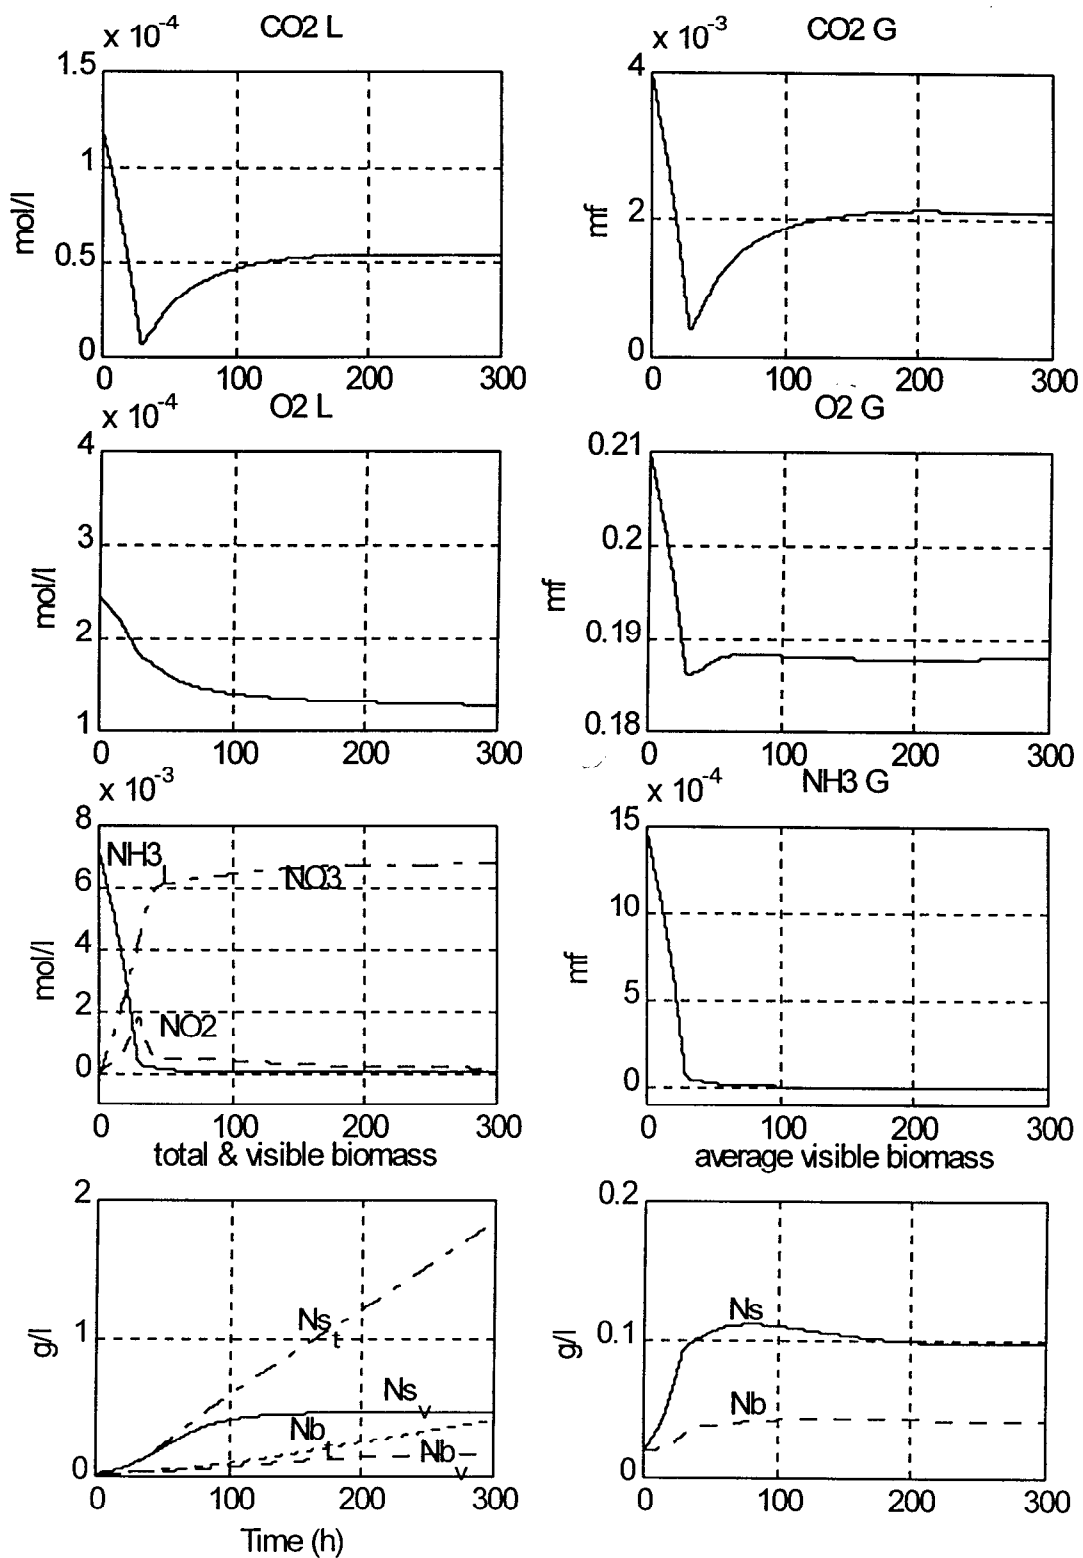

■ **Tank 5 of fixed bed :**

The 29 first hours are quite similar to those of tank 1. The NH_3 concentration becomes quickly null. The growth rate of global biomass N_s becomes null and the active biomass disappears progressively.

After its maximum at 2 mmol/l, NO_2^- concentration is getting null quickly (10 h). As for N_s , the biomass N_b is nearly null at the end of 300 h.

Remark : the NH_3 and NO_2^- concentrations are null because the consumption rates of these substrates in the maintenance reaction are not limited by a michaelian factor.

6. CHECKING THE MASS BALANCE

To test the software simulating the column, the mass balance of atom N is used : the incoming rate of N is compared to the sum of outgoing rate of N and of stocking rate of N in the column (parts A, B and C).

The top graph of figure 10 shows 2 temporal curves :

- the dash dotted curve is the incoming rate of N (NH_3 G and L) ;
- the continuous curve is the sum of the outgoing rate of N and of the derivative of the total amount of N in the column (NH_3 G and L, NO_2^- , NO_3^- , global (active + decay) biomass).

The distance between these 2 curves is distributed on 2 different scales : it is about 0,4 % during the exponential growth and nearly null otherwise.

7. CHECKING THE APPROXIMATION OF THE GAS/LIQUID EQUILIBRIUM

In order to estimate the error that is done when the non linear law of gas/liquid equilibrium is replaced by the linear relation (1), one need only to compare for each compound i the partition coefficient k_i to the ratio.

$$z_i = \frac{y_i}{x_i}$$

with :

$$y_i = \frac{a_i}{\sum a_i}$$

$$x_i = \frac{c_i}{\sum c_i}$$

where : a_i is the molar concentration in the gas phase

c_i is the molar concentration in the liquid phase at thermodynamical equilibrium

An other expression of z_i is :

ESA -ESTEC	MELISSA - Technical note 35.2		April 1998
	"Simplification of the dynamic model of the nitrifying compartment"		N° réf : 2034
ADERSA	10, rue de la Croix Martre 91873 PALAISEAU Cedex	Tel : (33) 01 60 13 53 53 E-Mail : adersa@adersa.asso.fr	Fax : (33) 01 69 20 05 63
			Disquette PC n°51 Page 20

$$z_i = \frac{k_i}{n_{l0} \cdot V_M} \cdot \frac{\sum c_i}{\sum a_i}$$

With the legitimate approximation $\sum c_i = n_{l0}$

$$z_i = \gamma \cdot k_i \quad \text{where} \quad \gamma = \frac{1}{V_M \cdot \sum a_i}$$

γ is independent of compound i.

The 3 bottom graphs of figure 10 show the evolution of γ all along the simulation for part A, tank 1 of the fixed bed and part C.

The mean value of γ is about 1.03, which means that the right partition coefficient k_i is overestimate of about 3 %. In order to compensate this overestimation, one only need to reduce of 3 % the right value of k_i in the simulations.

8. CONCLUSION

The equations (11), (12) and (13) are used to simulate the behaviour of the nitrifying column.

The smallest time constant of the initial system (equations (1) to (4)) is seen for NH_3 , whatever N_B , and is $\tau_2 = 2.10^{-6}$ hour (figure 5). The smallest time constant of the simplified system (equations (11) and (12)) is $\tau_1 = 10^{-2}$ hour. So, the computation time is divided by about 5000 when the simplified system is used. It could be still reduced for small value of the number of equivalent tanks of part B of the column, N_B ($N_B \leq 5$): in that case, τ_1 could be neglected versus τ_L for O_2 and CO_2 .

This work shows that the bio-physical complexity of the dynamical model built by LGCB, is not responsible of the huge time computation. Indeed this complexity, which makes the wealth of the model should be preserved. That is possible thanks to the mathematical simplification proposed here.

This simplification includes 3 aspects :

1. the substitution of the non linear law of the gas / liquid equilibrium by a linear approximative one (relation (1)). This substitution is equivalent to a non linear law where the partition coefficient would be increased of about 3 %. This over-estimation can be eliminated in reducing of 3 % the right values of the partition coefficient in the simplified model.
2. the elimination of the smaller time constant versus the bigger one. This simplification is quite legitimate and is invisible in the numerical results.
3. the Laplace transforms, used to explicitly solved the set of differential equations, needs the assumption of constant gaz and liquid flow rates at the input of the column.

This last aspect of the simplification involves a too restrictive assumption. An other way of simplification has to be looked for in a further study.

APPROXIMATIVE RELATION FOR GAS/LIQUID EQUILIBRIUM

The gas/liquid equilibrium of each compound i is characterized by the partition coefficient k_i :

$$k_i = \frac{y_i}{x_i}$$

where y_i = molar fraction of compound i in gas phase
 x_i = molar fraction of compound i in liquid phase

Here, the compounds involved are O_2 CO_2 NH_3 H_2O and N_2 .

Given : V_g volume of gas (in l)
 V_l volume of liquid (in l)
 n_{gi} number of mol of compound i in gas phase
 n_{li} number of mol of compound i in liquid phase
 V_M molar volume at pressure and temperature of the column
 a_i molar concentration of compound i in gas phase
 c_i molar concentration of compound i in liquid phase at thermodynamical equilibrium

Assumptions :

1. The total number of mols in liquid is the number of mols of water :

$$\sum_i n_{li} = n_{l0} \cdot V_l \quad \text{with} \quad n_{l0} = \frac{1000}{18} = 55.56 \text{ mol/l}$$

2. The gas are perfect :

$$\sum_i n_{gi} = \frac{V_g}{V_M}$$

Molar fraction and concentration are related by :

$$y_i = \frac{n_{gi} \cdot V_M}{V_g} = a_i \cdot V_M$$

				Page 25

$$x_i = \frac{n_{li}}{n_{l0} \cdot V_1} = \frac{c_i}{n_{l0}}$$

$$\Rightarrow a_i = \alpha_i \cdot c_i \quad \text{with} \quad \alpha_i = \frac{k_i}{n_{l0} \cdot V_M}$$

This last relation is the equation (1) of the system of the bi-phases substrates.

				Page 27

SIMPLIFICATION OF THE EQUATIONS SYSTEM OF THE BI-PHASES SUBSTRATES

The starting point of the resolution is the following set of equations (relations (5) to (8) of paragraph 3).

$$\left| \begin{array}{l} a = \alpha \cdot c \\ \phi = K(c - b) \\ V_L \cdot \frac{db}{dt} = (r + \phi) \cdot V_L + q_L \cdot d_L - q_L \cdot b \\ V_G \cdot \frac{da}{dt} = -\phi \cdot V_L + q_G \cdot d_G - q_G \cdot a \end{array} \right.$$

Cancellation of c and ϕ gives :

$$\left| \begin{array}{l} (K \cdot V_L + q_L) b + V_L \cdot \frac{db}{dt} = \frac{K \cdot V_L}{\alpha} \cdot a + V_L \cdot r + q_L \cdot d_L \\ \left(\frac{K \cdot V_L}{\alpha} + q_G \right) a + V_G \cdot \frac{da}{dt} = K \cdot V_L \cdot b + q_G \cdot d_G \end{array} \right.$$

Using the Laplace transforms :

$$\left| \begin{array}{l} (1 + \theta_1 p) \cdot b = \alpha_1 \cdot a + \alpha_2 \cdot r + \alpha_3 \cdot d_L \end{array} \right. \quad (A2.1)$$

$$\left| \begin{array}{l} (1 + \theta_2 p) \cdot a = \alpha_4 \cdot b + \alpha_5 \cdot d_G \end{array} \right. \quad (A2.2)$$

with :

$$\theta_1 = \frac{V_L}{K \cdot V_L + q_L}$$

$$\theta_2 = \frac{V_G}{\frac{K \cdot V_L}{\alpha} + q_G}$$

ESA - ESTEC	MELISSA - Technical note 35.2		April 1998

			Page 28

$$\alpha_1 = \frac{K \cdot V_L}{\alpha(K \cdot V_L + q_L)}$$

$$\alpha_2 = \frac{V_L}{K \cdot V_L + q_L}$$

$$\alpha_3 = \frac{q_L}{K \cdot V_L + q_L}$$

$$\alpha_4 = \frac{K \cdot V_L}{\frac{K \cdot V_L}{\alpha} + q_G}$$

$$\alpha_5 = \frac{q_G}{\frac{K \cdot V_L}{\alpha} + q_G}$$

p : the Laplace variable

Although the notations have not been changed with the Laplace transformation, the functions a, b, r, d_L and d_G are now functions of the Laplace variable p. (Before the transformation, they were functions of time).

Cancellation of a in (A2.1) and (A2.2) :

$$a = \frac{\alpha_4}{1 + \theta_2 p} b + \frac{\alpha_5}{1 + \theta_2 p} \cdot d_G \quad (\text{A2.3})$$

gives :

$$\begin{aligned} (1 - \alpha_1 \alpha_4) (1 + \beta_1 p + \beta_2 p^2) \cdot b \\ = \alpha_2 (1 + \theta_2 p) \cdot r + \alpha_1 \alpha_5 d_G + \alpha_3 (1 + \theta_2 p) \cdot d_L \end{aligned} \quad (\text{A2.4})$$

with :

$$\left| \begin{aligned} \beta_1 &= \frac{\theta_1 + \theta_2}{1 - \alpha_1 \cdot \alpha_4} \\ \beta_2 &= \frac{\theta_1 \cdot \theta_2}{1 - \alpha_1 \cdot \alpha_4} \end{aligned} \right.$$

ESA - ESTEC	MELISSA - Technical note 35.2		April 1998
	"Simplification of the dynamic model of the nitrifying compartment"		N° réf : 2034
ADERSA	10, rue de la Croix Martre	Tel : (33) 01 60 13 53 53	Disquette PC n°51
	91873 PALAISEAU Cedex	E-Mail : adersa@adersa.asso.fr	Page 29
		Fax : (33) 01 69 20 05 63	

Study of $y = 1 + \beta_1 p + \beta_2 p^2$:

Given :

$$y = \beta_2 \left(p^2 + \frac{\beta_1}{\beta_2} p + \frac{1}{\beta_2} \right)$$

Given p_1 and p_2 the roots of $p^2 + \frac{\beta_1}{\beta_2} p + \frac{1}{\beta_2}$.

$$\Rightarrow \left| \begin{array}{l} y = \beta_2(p - p_1)(p - p_2) \\ \text{and } p_1 \cdot p_2 = \frac{1}{\beta_2} \end{array} \right.$$

Given $\tau_1 = -\frac{1}{p_1}$ et $\tau_2 = -\frac{1}{p_2}$ such as $\tau_1 > \tau_2$.

The expression of y becomes :

$$y = \frac{\beta_2}{p_1 \cdot p_2} \cdot (1 + \tau_1 p)(1 + \tau_2 p)$$

$$\Rightarrow y = (1 + \tau_1 p)(1 + \tau_2 p) \quad (\text{A2.5})$$

So (A2.4) becomes :

$$\begin{aligned} (1 - \alpha_1 \alpha_4)(1 + \tau_1 p)(1 + \tau_2 p) \cdot b \\ = \alpha_2(1 + \theta_2 p) \cdot r + \alpha_1 \alpha_5 d_G + \alpha_3(1 + \theta_2 p) \cdot d_L \end{aligned} \quad (\text{A2.6})$$

As previously said in paragraph 3, for the compounds O_2 , CO_2 and NH_3 and for $1 \leq N_B \leq 50$, the two following approximations can be done :

$$\left| \begin{array}{l} 1 + \tau_2 p = 1 + \theta_2 p \\ (1 + \tau_1 p)(1 + \tau_2 p) = 1 + \tau_1 p \end{array} \right.$$

The relation (A2.6) becomes :

$$b = \frac{G_1}{1 + \tau_1 p} \cdot d_L + \frac{G_2}{1 + \tau_1 p} \cdot d_G + \frac{G_3}{1 + \tau_1 p} \cdot r \quad (\text{A2.7})$$

ESA -ESTEC	MELISSA - Technical note 35.2		April 1998
	"Simplification of the dynamic model of the nitrifying compartment"		N° réf : 2034
ADERSA	10, rue de la Croix Martre 91873 PALAISEAU Cedex	Tel : (33) 01 60 13 53 53 E-Mail : adersa@adersa.asso.fr	Fax : (33) 01 69 20 05 63
			Disquette PC n°51
			Page 30

with :

$$\left| \begin{array}{l} G_1 = \frac{\alpha_3}{1 - \alpha_1 \cdot \alpha_4} \\ G_2 = \frac{\alpha_1 \cdot \alpha_5}{1 - \alpha_1 \cdot \alpha_4} \\ G_3 = \frac{\alpha_2}{1 - \alpha_1 \cdot \alpha_4} \end{array} \right.$$

In the same way (A2.3) gives :

$$a = \frac{G'_1}{1 + \tau_1 p} \cdot d_L + \frac{G'_2}{1 + \tau_1 p} \cdot d_G + \frac{G'_3}{1 + \tau_1 p} \cdot r \quad (A2.8)$$

with :

$$G'_1 = \alpha_4 \cdot G_1$$

$$G'_2 = \alpha_5 + \alpha_4 \cdot G_2$$

$$G'_3 = \alpha_4 \cdot G_3$$

The relations (A2.7) and (A2.8), binding the inputs r , d_G and d_L , of the one part, and the outputs, a and b , of the other part, are first order transfers with the time constant τ_1 .

The inverse Laplace transforms allow to express the derivatives of a and b :

$$\frac{db}{dt} = \frac{1}{\tau_1} (-b + G_1 \cdot d_L + G_2 \cdot d_G + G_3 \cdot r) \quad (A2.9)$$

$$\frac{da}{dt} = \frac{1}{\tau_1} (-a + G'_1 \cdot d_L + G'_2 \cdot d_G + G'_3 \cdot r) \quad (A2.10)$$

Although the notations have not been changed with the Laplace transformation, the functions a , b , r , d_L and d_G are functions of time again, as they were before resolution through Laplace transforms.

The relations (A2.9) and (A2.10) are the relations (11) and (12) given in paragraph 3.

SOFTWARE OF THE SIMULATOR OF THE NITRIFYING COLUMN

The software is written in Matlab® language and is composed of the following programmes :

- . i_sim.m : initialization of the simulation (duration, configuration ...)
- . column.m : derivative equations of the column
- . calmu.m : calculation of μ , taking into account the limiting substrates.

It is saved in the directory :

c:\melissa\nitri\colonne5

function [mu,muX] = calmu(C)

global mumax maint Kl In Yx Nls Nis

% components of C :
%      1 : NH3
%      2 : NO2-
%      3 : O2
%      4 : HCO3-

% 1_ Computation of rmu = mu/mumax :
aa1 = C(1) * C(3) * C(4) / (Kl(1,1)+C(1)) / (Kl(3,1)+C(3)) / (Kl(4,1)+C(4));
aa2 = C(2) * C(3) * C(4) / (Kl(2,2)+C(2)) / (Kl(3,2)+C(3)) / (Kl(4,2)+C(4));
rmu = [aa1; aa2] ;
% 2_ computation of mu and muX :
mu = rmu.*mumax;
muX = rmu.*mumax + (1-rmu).*maint.*Yx;
